

CORE-CM PROJECT—SAN JUAN RIVER-RATON BASINS, NEW MEXICO FIELD SAMPLING PLAN

Prepared by the Characterization Team

June 2022

1.0 INTRODUCTION

In order to evaluate REE in coal and associated stratigraphic units in the San Juan and Raton basins, a variety of field sampling methods of solid and water are required. This Field Sampling Plan describes the field sampling and analyses that will be conducted as part of studies for the CORE-CM Project. The field sampling program will be carefully planned to meet the Data Quality Objectives (DQOs), minimize cost, and minimize the potential conflicts between the numerous investigations. Appendix 1 is a list of SOPs. Appendix 2 includes forms used during the sampling program. All of this information is in the Project Database. The specific fields and data collected have been determined by various PIs to be important to characterize the samples. A SQS database will be designed to store, manage, and interpret data.

2.0 REE SAMPLING PROGRAM METHODOLOGY

Representative samples will be collected from each coal field. Clays (including playas), black shales, beach placer sandstones, humates, and other stratigraphic units above, below, or near coal seams will be sampled as appropriate. Samples on Federal land do not require any permission for access and will be given higher priority for sampling. Coal waste and by-products will be sampled from active and inactive coal mines. The New Mexico State Land Office has granted permission to sample on state land and a permit is pending. Permission before sampling on private (including active coal mines and power plants) or Tribal lands will be obtained before sampling. Samples from each coal field (Table 1) will be collected.

Six types of samples will be collected:

- 1) Drill core of coal deposits
- 2) Stratigraphic profile of outcrops with coal seams
- 3) Adjacent strata with REE or other critical minerals potential
- 4) Samples of waste products from operating active mines, preparation plants, power plants and disposal sites (active and inactive)
- 5) Samples from Abandoned Mine Lands (AML) sites
- 6) Samples of water draining from mines and waste storage sites (including process waters), where available (Separate SOP will be written to collect water samples)

3.0 DATA QUALITY OBJECTIVES

The proposed field investigation will focus on the following objectives:

- 1) Basinal Assessment of CORE-CM Resources
 - a) identify and quantify the distribution of REE and CM in coal beds and related stratigraphic units in the San Juan and Raton basins
 - b) identify and characterize the sources of REE and CM
- 2) Basinal Strategies for Reuse of Waste Streams
- 3) Basinal Strategies for Infrastructure, Industries and Businesses
 - a) evaluate the basinal industry infrastructure and determine the economic viability of industrial upgrading
- 4) Technology Assessment, Development, and Field Testing
- 5) Technology Innovation Center
- 6) Stakeholder Outreach and Education

To meet these DQOs, the Characterization Team will implement this field sampling program. This sampling plan provides the detail sampling procedures to accomplish the work plan.

3.0 STUDY AREA

The study area includes the San Juan and Raton Basins in San Juan, Rio Arriba, Sandoval, McKinley, Cibola, Catron, Socorro, and Colfax Counties (Fig. 1, 2, Table 1). Field samples and drill core will be collected (Fig. 1, 2).

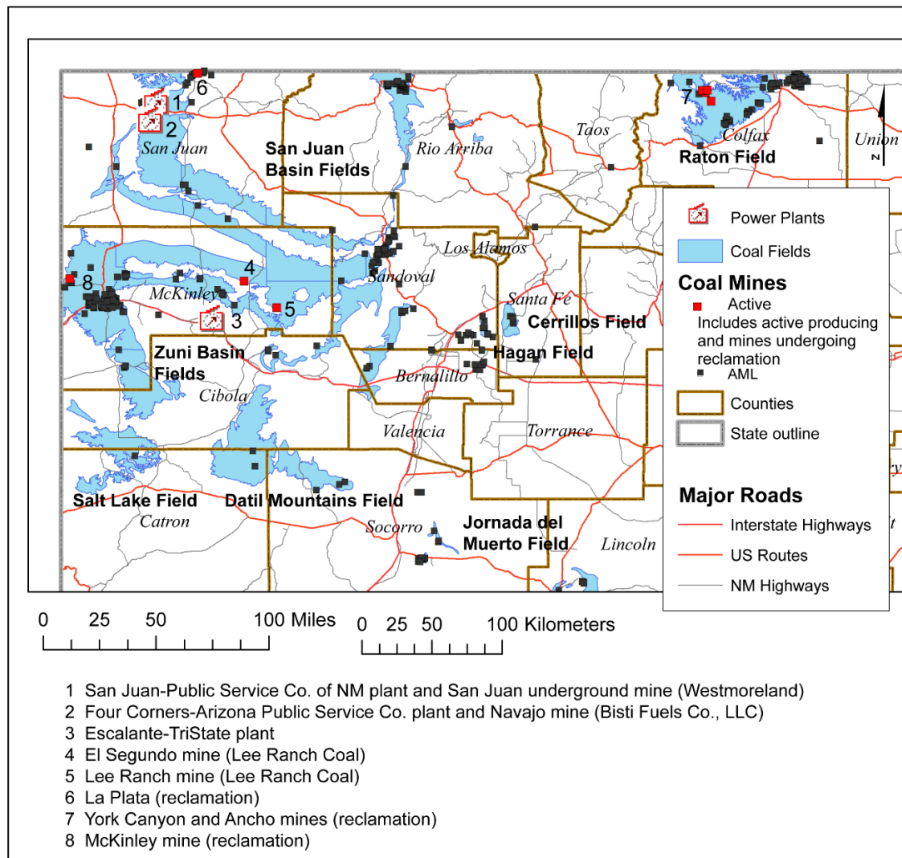

FIGURE 1. Coal fields, active mines, AML (abandoned mine lands) sites, and power plants in the San Juan and Raton Basins.

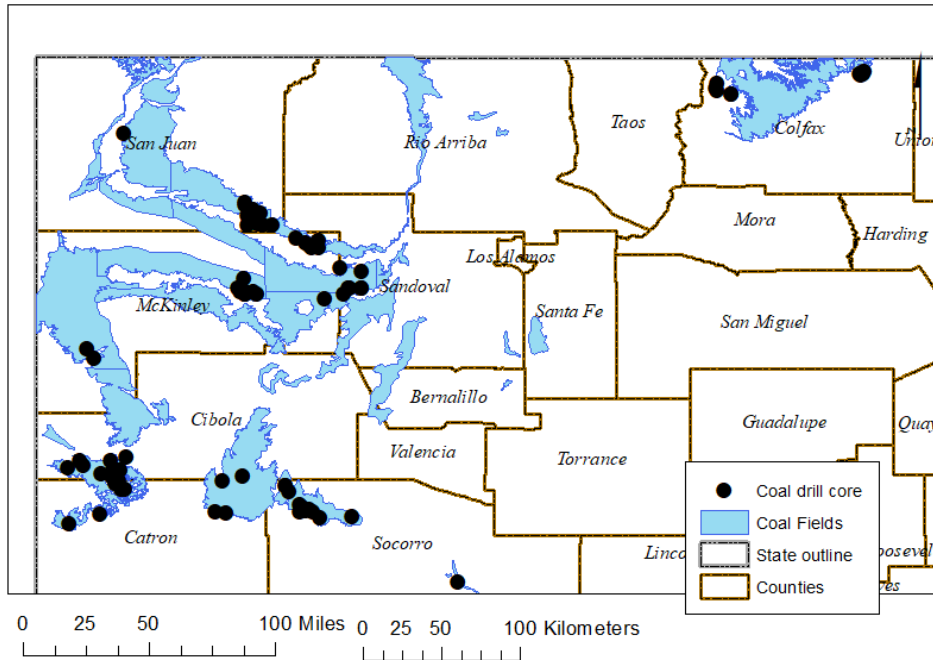

FIGURE 2. Coal fields and drill core in the San Juan and Raton Basins stored at the NMBGMR core facility.

TABLE 1. Coal fields in the San Juan and Raton basins, studied in this project, delineated by Hoffman (1996, 2017). District Id is from the New Mexico Mines Database (McLemore, 2010a, 2017). Representative samples will be collected from each coal field. Each field sample will be prefixed with an abbreviation representing each coal district. Each drill core sample will be identified by the hole number and depth. At least 3 samples will be collected from each coal field. Approximately 130 samples will be collected each year.

District id	District	Year of Discovery	Year of Initial Production	Year of Last Production	Estimated Cumulative Production	Formation
DIS257	Barker Creek coal field	1882		1905		Menefee
DIS150	Bisti coal field	1961	1980	1988	\$40,075,148.00	Fruitland
DIS259	Chaco Canyon Coal Field	1905	1905			Menefee
DIS260	Chacra Mesa coal field	1922		1945		Menefee
DIS174	La Ventana	1884	1904	1983		Menefee

DIS124	Zuni coal field	1916	1908	1926	\$16,010.00	Crevasse Canyon

4.0 INVESTIGATION APPROACH

The field characterization investigation has been designed to collect data to:

- 1) identify and quantify the distribution of critical minerals (CM), including rare earth elements (REE), in coal beds and related stratigraphic units in the San Juan and Raton basins in New Mexico (including coal, coal refuse, ash, coal seam, interstitial clays/shales, volcanic ash beds, acid mine drainage, associated sludge samples, mine dumps, other nonfuel carbon-based products, process waters, etc.)
- 2) identify possible sources of CM and REE in the basins
- 3) identify the coal mine and nonfuel carbon-based waste products that could contain CM and REE
- 4) characterize the CM and REE in these materials
- 5) determine the economic viability of extracting CM and REE from these materials

- 6) test and develop new technologies in identifying and quantifying CM and REE in high-fidelity geologic models.

To accomplish these objectives requires a Basinal Resource assessment of the San Juan and Raton basins as described below. The following tasks will be performed:

- 1) identify the stratigraphic units and coal mine waste products including coal, coal refuse, ash, coal seam, interstitial clays/shales, volcanic ash beds, acid mine drainage, associated sludge samples, mine dumps, other nonfuel carbon-based products, process waters, etc. that contain potential economic concentrations of CM and REE (Fig. 1, 2),
- 2) their location within the San Juan and Raton basins (Fig. 1)
- 3) estimate the quantity of each material contained within the San Juan and Raton basins. maps with locations of mines and exploration sites, mine features, waste and rock piles and areas of disturbance (using existing coal resource estimates as determined by the NMBGMR and USGS)

These tasks and supporting activities are described in this field sampling plan (FSP) and supporting SOPs.

5.0 RESPONSIBILITIES AND QUALIFICATIONS

The Senior Characterization Team members will supervise the sampling activities.

The Team Leader and Characterization Team will have the overall responsibility for implementing this sampling field plan. They will be responsible for assigning appropriate staff to implement this sampling field plan and for ensuring that the procedures are followed.

All personnel performing these procedures are required to have the appropriate health and safety training (see HASP). In addition, all personnel are required to have a complete understanding of the procedures described within this sampling field plan, and receive specific training regarding these procedures, if necessary.

All staff and assay laboratory staff are responsible for reporting deviations from this sampling field plan to the Team Leader.

6.0 PERMIT REQUIREMENTS AND NOTIFICATION

State Land Office permit is pending

7.0 LIST OF EQUIPMENT

See SOPs for list of equipment.

8.0 RELATED STANDARD OPERATING PROCEDURES

The procedures set forth in this plan are intended for use with the SOPs listed in Appendix 1.

9.0 FIELD ACTIVITIES

This section describes field activities that will be performed for the project and consist of the following activities:

- 1) Premobilization and site reconnaissance
- 2) Sample site selection
- 3) Surveying
- 4) Characterization sampling
- 5) Water sampling and determination of hydrologic conditions
- 6) Quality control and quality assurance procedures

Instructions for implementing these tasks are given in standard operating procedures (SOPs), which are included with this FSP. Any identified deviations from this FSP or SOPs will be documented and the Team Leader and Principle Investigators will be informed.

Premobilization and site reconnaissance

One or more reconnaissance trips may be needed to identify sampling sites and address any potential safety issues. All trips must be scheduled with Virginia McLemore.

Drill core

Drill core stored at the NMBGMR will be logged and photographed. NMBGMR has drill core of coal deposits from 146 locations scattered throughout San Juan and Raton basins (Fig. 2). Holes will be selected on the basis of coal field, completeness of the core, core description, radioactivity (measure of elevated REE), and use of LANL LIBS/RAMAN instrument. Personnel from LANL will use the LIBS/RAMAN instrument to determine mineralogical and chemical analyses of the core. Samples will be selected for laboratory analyses to compare to the instrument analyses. We will sample the coal seams and layers above and below the coal seams.

Field Sample Site Selection and Marking

Topographic and geologic maps will be imported into ArcGis along with land ownership databases. Sample sites will be selected using ArcGis and these maps on the basis of:

- 1) Safe access and sampling (no landslides or other disturbed slopes)
- 2) Active mines and power plants (Fig. 1)
- 3) AML sites (Fig. 1)
- 4) Outcropping coal seams with exposed units above and below the coal seam
- 5) Other strata with REE and critical minerals potential
- 6) Near known coal mines (coals are likely to be thick enough to mine)
- 7) On Federal or State land
- 8) Coals known to have uranium concentrations (McLemore, 1983)
- 9) Accessible (roads nearby)
- 10) Other criteria (such as near faults where fluids flow to potentially enrich coals with REE, near dikes or other intrusions where REE could be sourced, near known clay beds)
- 11) Coal wastes from active, reclamation, and AML sites
 - a) Fly ash, bottom ash
 - b) Waste rock piles (dumps)
 - c) AMD (acid mine drainage)
 - d) Processing waters

Selected sample locations will be marked with aluminum tags. Photographs will be taken (SOP 4). USGS guidelines will be used to select sample sites as appropriate (Appendix 3).

We will have two phases of sampling. Representative samples will be collected from the coal fields. LANL will then select phase 2 sample sites using machine learning techniques (LANL) to select sites to “fill in the gaps” for a complete basin assessment

Surveying

Conventional use of handheld GPS survey techniques will be used to locate samples; elevations will be taken from topographic maps. SOP 3 describes the procedures for GPS surveying.

SAMPLING

Different sampling strategies will be employed based upon the purpose of each sampling task. Field geologists with experience in the regional stratigraphy and in the recognition of altered and weathered rocks perform the sampling. The types of samples to be collected include:

- 1) Drill core of coal deposits (Fig. 2)
- 2) Stratigraphic profile of outcrops with coal seams (Fig. 1)
- 3) Composite or select samples of coal and other strata
- 4) Samples of waste products from operating active mines, preparation plants, power plants or owning the disposal sites (active and inactive) (Fig. 1)
- 5) Samples from Abandoned Mine Lands (AML) sites (Fig. 1)
- 6) Samples of water draining from mines and waste storage sites, where available (SOP 7)

All of the coal fields and major lithologic units using outcrop localities (overburden, waste rock piles, underlying rocks, and other country rocks), drill core, and waste rock piles, will be sampled as appropriate. SOP 5 describes the procedures for sampling outcrops, rock piles, and drill core (solid samples).

A standardized protocol will be followed after each sample is taken (SOP 2). At each site, a select, grab, or bulk sample of rock or other material is collected for petrographic study and geochemical analyses that is representative of the DQO being addressed. Radioactive readings will be taken using a scintillometer (REE locally are found in areas of higher radioactivity). A hand specimen also is collected for thin section and archived. Each sample is collected in a separate bag or bucket, assigned a unique number (field id), and logged on a field description form (Appendix 2). Selected sample sites are marked in the field and a digital photograph (SOP 3, Appendix 2) is taken at all localities. Photographs provide visual record of the sample site; the photograph form identifies site specifics, provides basic location and other data about the photograph (SOP 3). Location information by GPS, type of sample, and field and laboratory petrographic descriptions will be collected (Appendix 2). Each sample will be clearly identified. Geologic observations are recorded on the field description form and each site is located on a map. A global positioning system (GPS) reading is recorded as well (SOP 3). Hand specimen description provides a record of what was collected, aids in petrographic description, and provides information on sample for the labs (high S may be treated differently than low S) (Appendix 2). The hand specimen description is the preliminary data required to determine what samples need specific detailed analyses to meet the DQOs. NMBGMR will archive all samples for potential future studies.

The samples are transported from the field to NMBGMR, where each sample is prepared for analyses. Selected samples will be cut and chips will be sent for preparation of polished thin sections. The prepared samples are then sent to a laboratory for chemical analyses. NMBGMR standards are submitted blind to the commercial laboratory with each sample batch to assure analytical quality.

Petrographic analysis and mineral identification are important in differentiating various rock units, determining rank and intensity of alteration, determining chemistry of alternating fluids, describing cementation, and determination of paragenesis of mineralization, alteration, and cementation. Alteration rank is based upon the mineral assemblages, which infers temperature, pressure, and permeability conditions at the time of formation. Petrography will be performed using standard petrographic and reflected ore microscopy techniques (Appendix 2). Mineral concentrations will be estimated using standard charts and data. Estimates of both primary and alteration minerals will be determined, cementation described, and the alteration intensity will be determined from the concentration of alteration minerals. Forms are in the database. Digital photographs will be taken (SOP 3).

Sampling Procedure

- 1) Collect samples of all of the major lithologic units using outcrop localities (ArcGis and geologic maps), drill core (Fig. 2), and AML waste rock piles (Fig. 1). The numbering system we will use will be COAL followed by sequential numbers. Samples of clay, shale, weathering profiles should be collected wherever possible and given unique sample numbers. Location data is entered into **waypoint form** (Appendix 2).
- 2) Record geologic observations on the **sample description form** (Appendix 2).
- 3) Record site description on the **sample description form** (Appendix 2).
- 4) Locate each site on a topographic map and take a GPS reading (NAD 27, UTM) and enter on the **waypoint form (SOP 3)** (Appendix 2).
- 5) Photograph sample site (information recorded on **photograph form**, SOP 4, (Appendix 2). The numbering system for the photograph will be the field identification number, followed by P1 sequentially, Ros1-P1. Photographs will be taken at highest resolution as jpeg or tif files and stored in separate folders corresponding to their image type.
- 6) Archive hand sample prior to sample preparation.
- 7) All data are entered into the project database.

Surface water and seep sampling

Should any surface water or seeps be encountered in or near the rock piles, sampling could occur according to SOP 7.

10.0 ANALYTICAL ACTIVITIES

This section describes analytical activities that will be performed for the Project and consist of the following activities:

- 1) Sample preparation
- 2) Bulk mineral identification
- 3) Geochemical and statistical analyses
- 4) Quality control and quality assurance procedures

Sample preparation and analysis (solid)

- 1) Hand samples will be sawed in half, photographed and archived.
- 2) Solid samples cut for thin sections (information recorded on **sample preparation form**, Appendix 2, SOP 8).
- 3) Polished thin sections of selected samples will be prepared by a commercial laboratory.
- 4) Polished probe sections of selected samples for microprobe analysis will be prepared by NMIMT lab and examined for mineralogy (**petrographic description form**, SOP 24, Appendix 2,).
- 5) Photograph taken of thin sections (information recorded on **photograph form**, SOP 4, Appendix 2,).
- 6) Selected thin sections and other samples for electron microprobe study (SOP 26).
- 7) Samples analyzed for bulk mineralogy using XRD and recorded in **mineralogy table** (SOP 27).

Bulk mineral identification by XRD

Bulk mineral identification can be used to identify minerals present in quantities greater than approximately 3%. Altered, unaltered, and mineralized samples, including select samples of cement, will be powdered and analyzed by X-ray diffraction (XRD).

Chemical analyses

Chemical analyses of solids (ICP, XRF, other, SOP 30, 31, 28) provide detailed concentrations of abundance of specific elements that directly relate to mineralogy and water quality. Chemical analyses of water samples provide information on pore water chemistry and relates to the sequence of alteration (SOP 30, 31).

1. Solid samples analyzed for major and trace elements using XRF, ICP, and other methods
2. Water samples analyzed for major and trace elements using ICP and other methods

Paste pH and conductivity

Paste pH and paste conductivity (SOP 11) are used to evaluate the geochemical behavior of mine rock materials subject to weathering under field conditions and to estimate the pH and conductivity of the pore water resulting from dissolution of secondary mineral phases on the surfaces of oxidized rock particles.

Electron microprobe

Electron microprobe analyses (SOP 26) provide mineral identification, specific mineral chemistry, relationships between the minerals, provide information on how minerals are altering, and what new minerals forming at a microscopic level. Probe analysis can identify rims around sulfide minerals that could inhibit alteration of the mineral.

Criteria for selection: after petrographic analysis, clay mineralogy

11.0 QUALITY CONTROL AND QUALITY ASSURANCE PROCEDURES

Procedure—A standardized protocol will be followed after each sample is taken and chain of custody and request for analyses will be completed. Location data by GPS, type of sample, and

field and laboratory petrographic descriptions will be collected. Each sample will be clearly identified. The samples will be transported from the field to NMBMMR. The samples will be sent to a laboratory for analyses.

For each batch of 25 samples, 1 set of duplicate samples with different sample_id numbers will be run. NMBGMR internal standards will be submitted blind to the laboratory with each sample batch of 25 samples to assure analytical quality. NMBGMR will archive a split of all samples for future studies.

Accuracy and precision of data—The accuracy of the data is how close the measured value is to the true value. Analyzing certified standards as unknown samples and comparing with known certified values monitors accuracy. The precision of an analysis is the repeatability of a measurement. Precision is monitored by multiple analyses of many sample duplicates and internal standards. Estimates of accuracy and precision will be determined. Errors due to accuracy will be determined by multiple analyses of commercial standards for which accepted values are known. Errors due to precision will be determined by multiple analyses of selected sample splits, as well as multiple analyses of standard samples. There are numerous reasons why duplicate samples and/standards do not always agree. Some samples, such as rhyolite and andesite, grind into powder more easily than other samples, such as stream-sediment and rock pile samples. Fusion techniques required for XRF analyses vary from lab to lab and may also differ between different personnel that could result in variations between sample pairs. Analytical error is higher for analyses with concentrations close to the detection limit. In addition, mine samples and alluvium, such as the Capulin standard (CAP-MLJ-0001), are very heterogeneous and difficult to completely homogenize.

Another problem encountered with mine samples, is the variability of sample collection. Only trained geologists will collect the AML samples using the exact procedures to avoid variations between sample collectors. In addition, three samples will be collected at two separate sites by one sampler to estimate sample heterogeneity and assigned different field_id numbers.

12.0 DATA MANAGEMENT

Data for the Project will be obtained from a combination of sources, including field and laboratory measurements. The process of collecting and managing data is a coordinated effort (described in SOP 1) and will be conducted by project staff and laboratories working closely together. Laboratory data will be provided, when appropriate, in electronic form, in addition to the required hard-copy analytical data package. Data quality will be examined (SOP 1) before results are presented or used in subsequent activities. The laboratory will confirm sample receipt, sample condition, and required analyses. All pertinent information about each sample will be recorded.

13.0 SAMPLING SCHEDULE

Preliminary field reconnaissance December 2021.

14.0 ANALYSES SCHEDULE

As samples are collected, sample preparation and analyses will occur.

15.0 FIELD DOCUMENTATION

Forms will be used to record field and laboratory data (Appendix 3). These forms include:

- 1) Sample description form
- 2) Photograph form
- 3) Drill log

All forms that are completed by hand and all field forms will be archived in a binder in Socorro for future reference. Data will be immediately entered into the database. Copies of the database forms after completion also will be stored in binders.

Geologic observations and site description are recorded on the **sample description form**. Each site is located on a topographic map and a GPS reading taken (NAD 27, UTM) (SOP 3) and entered on the **sample description form**.

Photographs are taken of sample site (SOP 4; information recorded on **photograph form**). Photographs will be taken at the highest resolution as jpeg or tif and stored in separate folders corresponding to their image type.

Sample Archival and Disposal

All solid samples will be collected and archived at NMBGMR for potential future evaluation. Groundwater, surface water, and microbe sample aliquots will not be archived as a part of the study for future analysis or consideration. Any water sample volume not consumed during sample analysis will be disposed of by the laboratories as described in the laboratory QAM, and in accordance with all applicable rules and regulations.

18.0 HEALTH AND SAFETY

The site health and safety plan (HASP) will be followed by all contractors and subcontractors working on the site. It is the policy of New Mexico Tech to provide a safe and healthful work place for all employees, subcontractors, and clients in compliance with MSHA requirements. Telephone contacts are in Appendix 2.

Safety shall take precedence over expediency or short cuts. It is a condition of employment that all employees and subcontractors work safely and follow established safety rules and procedures. All injuries, vehicle accidents, and incidents with potential for injury or loss will be investigated. Appropriate corrective measures will be taken to prevent recurrence, and to continually improve the safety of the work place. Molycorp has a mandatory drug testing program that all personnel working on the property must follow.

APPENDIX 3 Guidelines from the USGS Circular 735

1. The judgment of the geologist must be applied toward obtaining samples which will be most representative of the coal bed.
2. Only samples of fresh or unweathered coal should be submitted for analysis, preferably collected from a newly exposed mine or outcrop face or from a drill core. The samples should be shipped to the laboratory within a few days after collection to minimize the effect of oxidation and exposure to air on the moisture content and on the forms of sulfur.
3. The objective should be to obtain a complete channel sample or core of the minable bed; if the coal bed is more than 5 feet (1.5 m) thick, a good rule-of-thumb is to collect one sample of each 5-foot (1.5-m) interval of coal (for example, four samples of a bed 20 ft, or 6 m, thick). Special-type samples (prominent fusain band or pyrite lens, for example) will also be analyzed at the discretion of the geologist.
4. Generally, 4 to 5 pounds (1.8 to 2.3 kg) of coal should be included in each sample; for rock samples, 2 pounds (0.9 kg) is sufficient.
5. A satisfactory channel sample, for example, can be obtained from a coal bed in a mine or outcrop by first exposing a new, fresh face of the coal, then chipping an approximately 3-inch by 3-inch (7.5 cm by 7.5 cm) channel downward from the top of the bed with a chisel or pick-point hammer, producing coal fragments 2 inches (5 cm) or less across. Positioning a horizontal plastic sheet below the level of channel cutting is sometimes helpful, particularly if coal accumulates in excess of the desired sample size, and cone-and-quartering separation of the coal is needed to obtain the representative sample.
6. Plastic bags (10 ´ 15 in., or 25.4 ´ 38 cm, or larger; thickness 0.006 in. or 0.15 mm) or buckets should be used for the sample, and care should be taken to avoid contact of the coal with metal during and after collecting sample (the use of a geologic hammer, of course, cannot be avoided); sample number, date of collection, and key description should be written with a felt-tipped marker pen (permanent ink) on each bag/bucket, and on a label attached to the tie on the bag.

7. A rule-of-thumb should be never to collect just a single sample from one locality--always collect two samples, or, if a mine face is several hundred yards (metres) long, collect three channel samples. The main reasons for collecting two or three samples are that short-distance compositional changes can be assessed and that possible analytical errors can be spotted.
8. Core samples of coal are better than samples of weathered coal, but contamination by drilling fluids generally makes trace-element analysis unreliable. Name and composition of drilling fluids used should accompany list of core samples submitted for analysis.
9. Shale splits, siltstone partings, or bone coal less than a few inches (5-10 cm) thick generally should be included in a channel sample if it is probable that this material will be included in mined coal. Special samples of these non-coal materials should also be collected, based on the judgment of the geologist, to determine their possible contribution to abnormal element concentrations.
10. If project objectives include the obtaining of knowledge of coal shipped or of plant feed, extra care should be taken to collect at least two representative raw coal, cleaned coal, blend-pile, and conveyor-belt samples. Such sample sets should include, where possible, representative samples of the sink-fraction of washed coal, and of furnace-bottom ash and fly ash from precipitator and scrubber units.
11. Where geochemical data on seatrock or underclay and overburden rock are desired, representative samples should be collected, according to the preceding guidelines. In collecting overburden samples, one of two methods may be preferable, depending on local conditions: (a) Channel samples of 5- or 10-foot (1.5- or 3-m) intervals; or (b) two samples of each lithology, which can be related to measured sections and assigned weighted values.
12. If permission to sample is obtained from a company, the offer should be made, and the promise kept, to provide the company with a copy of the analytical results as soon as they are completed; where possible, obtain available analytical data from the company for comparison with your analyses. It should be made clear to the company or landowner that the analyses of your samples will be part of the public record; the collection of samples which requires a promise to withhold analyses on a "company confidential" basis should be done only for compelling scientific purposes.
