MEMO

TO: Frank E. Kottlowski, Director  
FROM: Sam Thompson III, Petroleum Geologist  
SUBJECT: Open-File Report No. OF-140

As we discussed, the following report from GeoChem Laboratories, Inc. is to be placed in the Bureau Open-File:

OF-140 Hydrocarbon source-rock evaluation study, Hachita Dome, Inc. No. 1 Tidball-Berry Federal well, Hidalgo County, New Mexico, by Paul Tybor, GeoChem Laboratories, Inc., 1981, 13 p. (including 2 p. text, 8 tables, 2 charts)

Readers should note that the T-Max (°C) shown on Summary Table I and on Table II is a laboratory determination made during pyrolysis, and is the temperature at which volatile components are cracked from the kerogen in the sample. This temperature usually ranges between 420°C and 550°C. Although it is an indication of thermal maturity, this laboratory measurement is not an estimate of the maximum paleotemperature.

Mr. Sam Thompson III  
New Mexico Bureau of Mines &  
Mineral Resources  
Socorro, New Mexico 87801

Dear Mr. Thompson:

Enclosed please find the results of the organic geochemical analyses performed on thirty-eight (38) well cuttings samples from the Hachita Dome Inc. No. 1 Tidball-Berry Federal well, located in Hidalgo County, New Mexico.

Upon arrival at GeoChem the samples were logged in under GeoChem Job Number 1971, followed by the sample sequential number -001 to -038, and submitted to the following geochemical analytical program:

DISCUSSION OF THE RESULTSA. Thermal Maturity of Sediments

The Paleozoic sediments analyzed from this well range in thermal maturity from a mature Maturation Index Stage 3- at 640+ feet, within the Mississippian Escabrosa formation, to a very mature Maturation Index Stage 3+ at 2560+ feet, within the Ordovician El Paso formation.

The sediments within the Escabrosa formation are considered to be within the oil generating zone. Below the Escabrosa formation, within the Devonian Percha Shale, the maturation profile for this well, increases to a very mature level and remains at this level to total depth. At this very mature maturation level, these sediments are interpreted to be beyond the "oil window", in the wet gas-condensate generating zone.

These maturity interpretations were based on the variations in the coloration of the kerogen isolated from these samples (Table V). Vitrinite reflectance (Table VI; histogram) was performed on one sample (1971-019), however, we interpret that the results of this analysis represent reworked organic matter.

B. Hydrocarbon Source Characterization of Sediments)

With the exception of the lower portion of the Percha Shale, all of the Paleozoic sediments analyzed from this well are organic-lean, with poor hydrocarbon source characteristics.

The lower portion of the Percha Shale has a very mature, good wet gas-condensate source character.

This interpretation is based on the fair to good amounts of organic matter analyzed (Table I), which is comprised predominantly of the gas-prone woody organic matter type (Table V). This interval, represented by sample 1971-019, yielded fair amounts of C<sub>15+</sub> total hydrocarbon (407 ppm; Table III-B). This data indicates that these lower Percha Shale sediments do contain liquid (condensate) hydrocarbon generating capability.

Should you have any questions concerning this study, or if we may be of further service, please feel free to contact me.

Sincerely,

Paul Tybor  
Project Coordinator  
GEOCHEM LABORATORIES, INC.
