August 1981

ABSTRACT

The Pinehaven 7.5 minute quadrangle is located approximately 8 mi south of Gallup. Four stratigraphic units are found in the area; the Gallup Sandstone, the Crevasse Canyon Formation, the upper Bidahochi Formation, and Quaternary Alluvium. The majority of the coals present belong to the Crevasse Canyon Formation, with a few coals present in the Gallup Sandstone. The thickest, near-surface coals are found in two horizons within the Crevasse Canyon Formation.

Coals are present in a lower horizon which occurs directly above the Gallup Sandstone and are high volatile bituminous B or C in rank. The coals of the upper horizon, located in the upper portion of the Crevasse Canyon Formation, are of lower grade, having a rank of subbituminous A. Outcrop data is sparse; however, sixteen drill holes provide coverage for reserve calculation for most of the quadrangle. Reserves for the measured and indicated categories are calculated to be 34.65 million tons and 146.25 million tons respectively. These coals are low in sulfur, but may have as much as 40% ash. About 41% of the coal is owned by the Navajo tribe and 20% is owned by the Zuni tribe. The federal government owns 26% of the coal. The remaining 13% of the coal rights are held by private individuals and the State of New Mexico.

INTRODUCTION

LOCATION--The Pinehaven quadrangle lies 8 to 17 miles south of Gallup, New Mexico, between State Highway 32 on the west and the Nutria Monocline and the Zuni Mountains on the east (fig. 1). The area is almost equally distributed over four townships, Townships 12 and 13 N., and Range 17 and 18 W. in southwestern McKinley County.

The only paved road within the study area connects the small Navajo community of Bread Springs with State Highway 32. This road passes through the northwestern quarter of the quadrangle. Numerous dirt roads, some well maintained, provide access to nearly all parts of the quadrangle.

GEOGRAPHY--Ubiquitous but widely spaced dwellings, the majority inhabited by Indians, are present in the quadrangle. The community of Pinehaven is located in the northeastern part of the area along the road to McGaffey. The southeastern quarter of the quadrangle lies within the Zuni Reservation while the northeastern quarter includes the western fringes of the Cibola National Forest.

Three drainage systems and their tributaries carry water from the area and eventually empty into the Little Colorado River. Tributaries of Bread Springs Wash drain the far northern edge of the area. Whitewater Arroyo crosses the area from northeast to southwest and drains most of the central portion of the quadrangle. The southeastern portion of the area is drained by tributaries of the Rio Nutria.

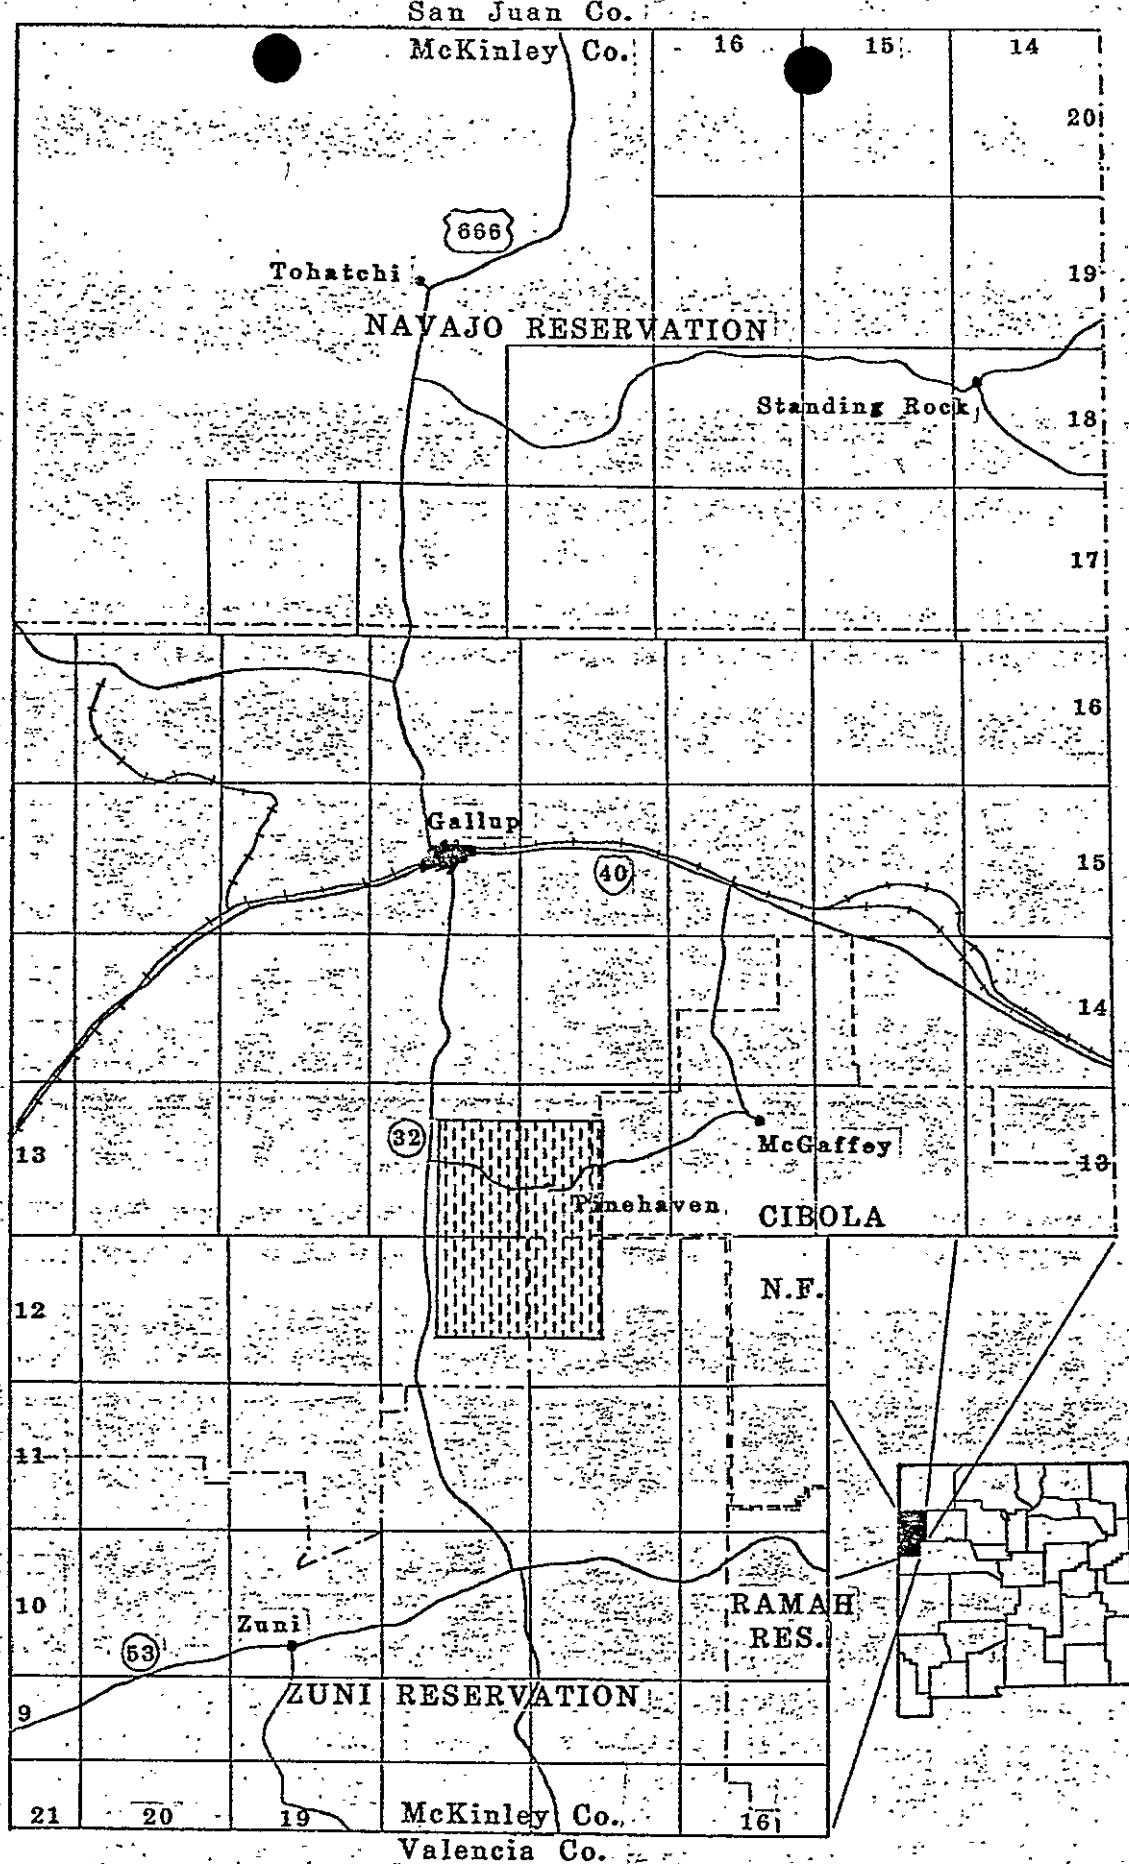

Figure 1--Location of Pinehaven quadrangle.

The streams have deeply dissected a gently westward sloping plateau that has an average elevation of about 7,300 ft above sea level. The old plateau surface now stands as much as 350 ft above the valley bottoms, producing a rugged terrain. The maximum elevation of 7,740 ft above sea level occurs in the northeast corner of the quadrangle while the lowest elevation, 6,820 ft, occurs in the southeastern part.

VEGETATION--The rocky mesa tops and canyon sides generally support a pinon-juniper forest with some scattered stands of ponderosa pine and scrub oak, with shrubs, grasses, and cacti providing the understory. The valley bottoms, with their deep soil, are characterized by grass-shrub vegetation alone. The vegetational boundary between grass-shrub and woodland areas often marks the contact between alluvial valley fill and exposures of bedrock on the canyon sides.

PREVIOUS WORK--The geology of the Pinehaven area had attracted the attention of investigators long before New Mexico became a state. Gilbert (1875) made an early reconnaissance study of the geology and is attributed with naming the Nutria Monocline. Dutton (1885) also reported on the general geology and structure of the Gallup-Zuni basin and noted the presence of coal in the region. Later reconnaissance studies of the structure and geology of this area were made by Darton (1910; 1922; and 1928) and Gregory (1917).

Schrader (1906) and Shaler (1907) made the first reconnaissance studies directed specifically toward coal deposits in the region. They produced preliminary maps and gave a few

measurements on the thickness and quality of coal in nearby Gallup and Zuni. Sears (1925) produced the first detailed report on the structure, stratigraphy and coal geology of the Gallup-Zuni area, and included in his report some earlier unpublished work by D.E. Winchester on coals on the Zuni Reservation. Sears subdivided the Mesaverde Formation in the Gallup area into the Gallup Sandstone Member, the Dilco Coal Member, and the Allison Barren Member, in ascending order. A reconnaissance of strippable coals in the Zuni area was done as a part of the San Juan Basin study (Shoemaker, et al, 1971). Reconnaissance and photogeologic mapping of the Gallup area by Hackman and Olson (1977) has updated the New Mexico geologic map of Dane and Bachman (1965).

Pike (1947) measured sections from this area for his landmark paper describing the regional intertonguing relationships between the marine and non-marine rocks of Upper Cretaceous age. He showed that the Mesaverde section thickens southward from Gallup at the expense of the underlying Mancos Shale in a more systematic approach than earlier investigators.

Allen and Balk (1954) revised Sears' terminology for the Gallup area Mesaverde rocks by raising the Gallup Sandstone to formational rank, and proposing a new formation the Crevasse Canyon Formation to include the overlying coal-bearing and barren members, including the Dalton Sandstone Member. In so doing, the Mesaverde was elevated from formation to group status. This terminology was formalized by Beaumont, Dane, and Sears (1956) and in addition, the Allison Barren Member was assigned to the Menefee Formation.

Papers by Beaumont (1957), Dane, Bachman, and Reeside (1957) and Molenaar (1973, 1974) discuss the stratigraphy, lithology, facies, and correlation of the Gallup Sandstone and associated formations. A good summary of Upper Cretaceous stratigraphy of the Four Corners area is provided in O'Sullivan, Repenning, Beaumont, and Page (1972).

SCOPE OF PRESENT STUDY--The work for this report is the result of a cooperative project with the Conservation Division of the U.S. Geological Survey and the Minerals Department of the Navajo Tribe. Most of the funding was provided under U.S. Geological Survey Grant 14-08-0001-G-570. This report presents the data from five months of detailed field mapping at 1:24000 scale and the subsequent drilling of several shallow drill holes. Analyses of core samples provide information on the chemical properties of fresh coals in the area. Coal resources were calculated following the parameters outlined in U.S. Geological Survey Bulletin 1450-B (1976). In addition to geologic information, a summary of land and mineral ownership are provided along with the history of coal mining and prospecting of the Pinehaven area.

ACKNOWLEDGMENTS--The many residents of the Pinehaven area are thanked for giving permission to enter their lands for geologic mapping. Thanks are also extended to the Zuni Indians, particularly Shirley Belson and Governor Robert Lewis, for granting permission to work on the Upper Nutria part of the reservation.

Messrs William Armstrong and Aktar Zaman of the Navajo Tribe Minerals Department arranged to work cooperatively on tribal lands

and kindly provided geologic and land ownership information and assisted with drilling entry problems. Messrs. Andrew Livingston of Bokum Resources, Inc., Rajendra Reddy of Carbon Coal Company and Peter Mattson of Utah International, Inc., graciously supplied drilling data from company files. Mr. Ijaz Khan of the Navajo Tribe Water and Sanitation Department provided drilling data from tribal water wells in the area. Ms. Idita Claymore and her staff at the Southwest Title Plant of the Bureau of Indian Affairs kindly provided access to their files so that patterns of mineral and surface ownership could be determined.

Help with the mapping was provided by Luis Martinez, of the State Bureau of Geology, and Gary Massingill, formerly with the New Mexico Bureau of Mines and Mineral Resources. Frank Campbell aided in compilation of the final report. Finally, the assistance of the U.S.G.S. Conservation Division staff of New Mexico, specifically Wayne Lambert and Norman Wingard, was most helpful in completing this study.

GEOLOGIC STRUCTURE

The Pinehaven quadrangle is situated within a broad shallow depression extending off the southwestern part of the San Juan Basin. This depression, the Gallup sag (Hackman and Olson, 1977), is bounded by the Defiance Monocline on the west and the Nutria Monocline on the east. The Gallup sag is an asymmetrical depression with its axis located very close to its eastern edge; the west limb is broad and gently sloping, while the east limb is

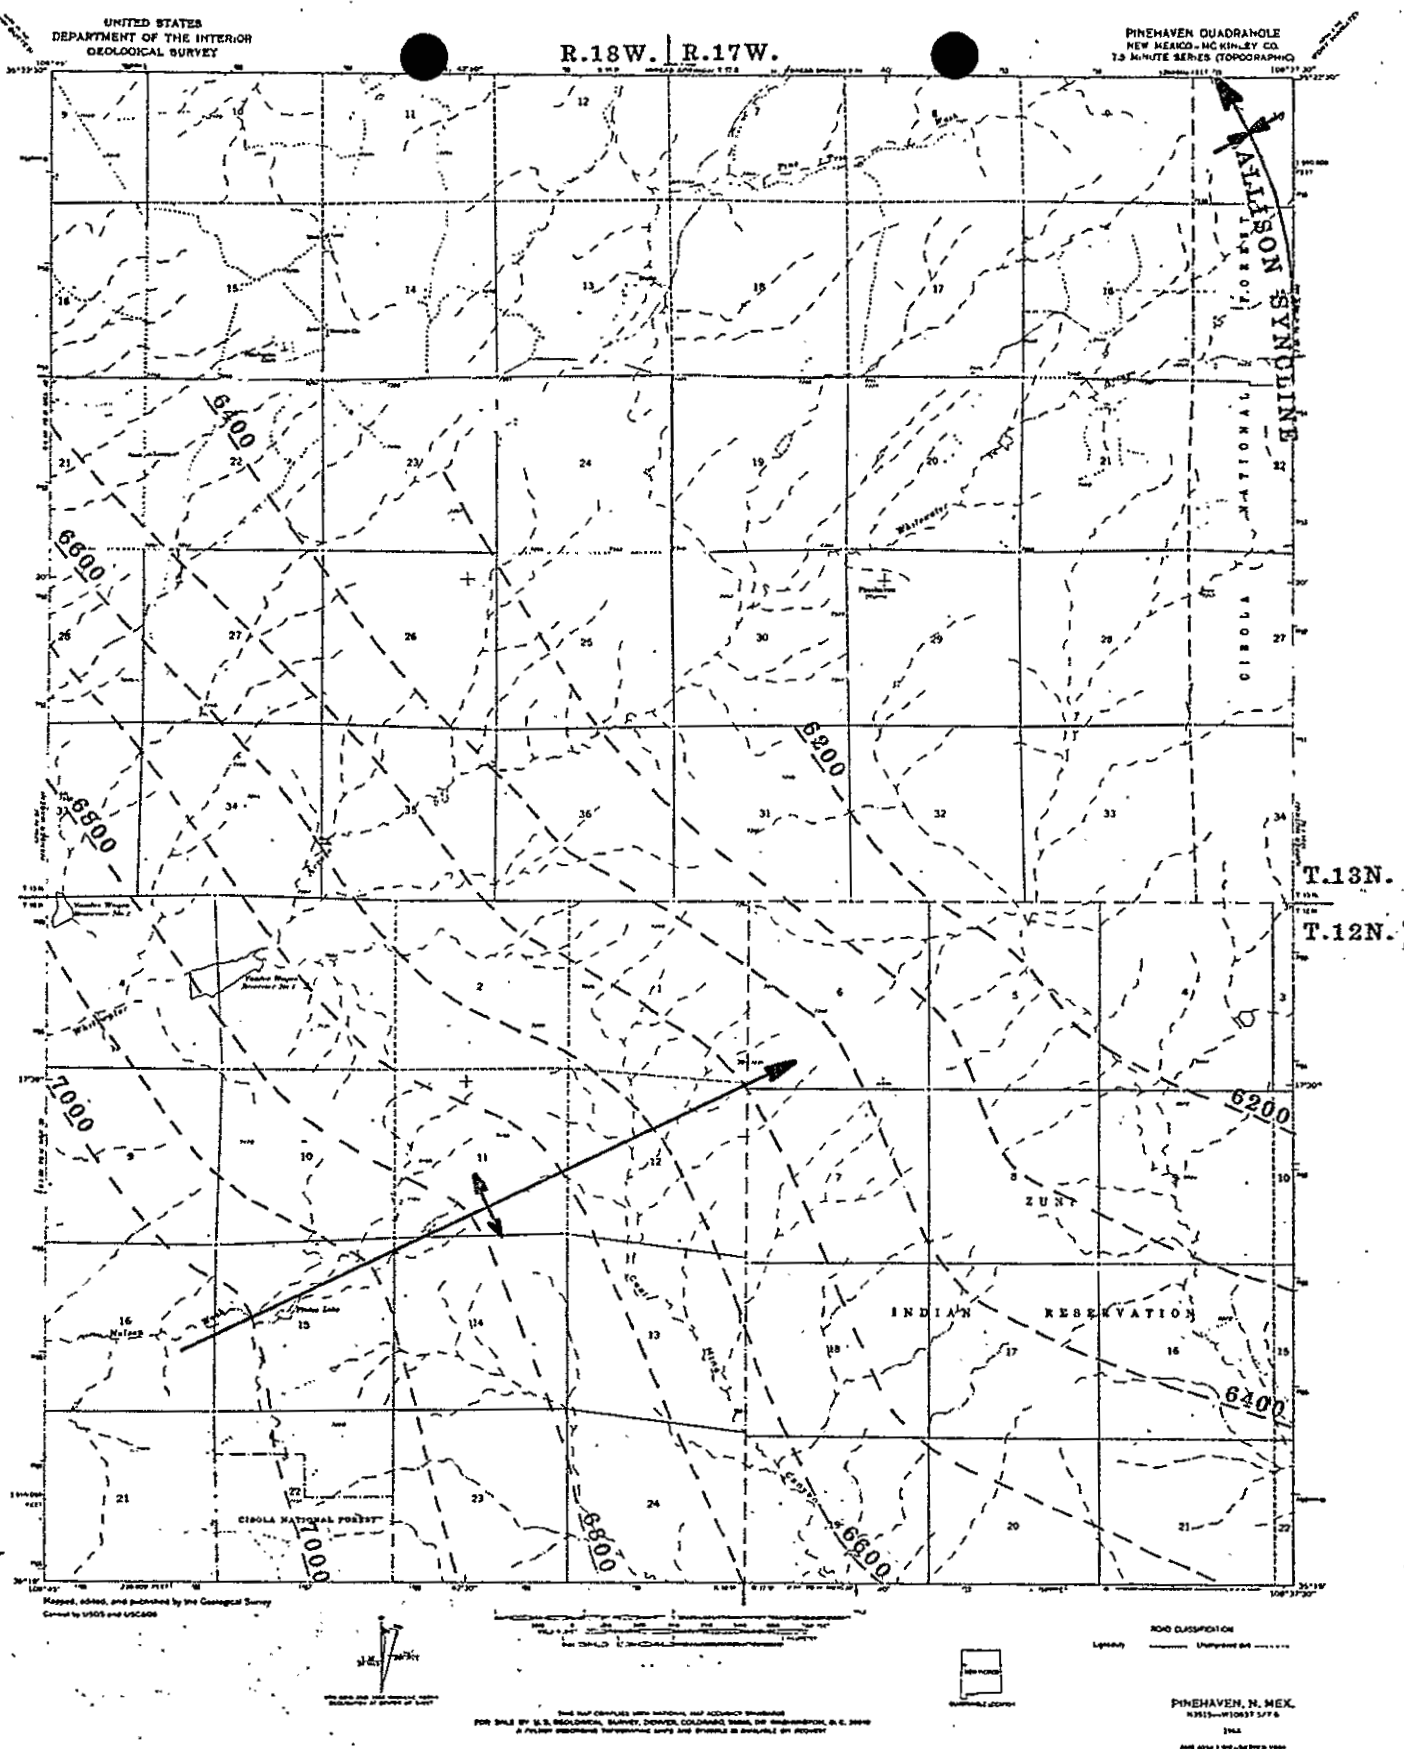

Figure 2--Structure contour on top of Gallup Sandstone.
(contour interval 100 ft, datum is sea level)

narrow and steep. The axial structure of the Gallup sag is called the Allison syncline (Fig. 2). Complicating the overall asymmetrical sag or synclinal structure are a number of gentle anticlines and synclines which tend to parallel the north-south structural trend.

The Pinehaven quadrangle lies along the broad western limb of the Allison syncline with the dips of the area ranging from 2 to 12 degrees to the northeast with and averaging 5 degrees. A gentle northeast plunging anticlinal flexure (Fig. 2) occurs in the southwestern quarter of the area and creates some northwesterly dips there. One normal fault, trending N. 15 E., is exposed in sec. 16, T. 12 N., R. 18 W. and has about 20 ft of displacement with the east side down relative to the west.

GENERAL STRATIGRAPHY

There are only a few stratigraphic units exposed in the study area. The youngest is Quaternary alluvium. The only Tertiary unit is the Bidahochi, which can attain a thickness of 180 ft. Two Cretaceous units, the Crevasse Canyon (possibly 1500 ft), and the Gallup Sandstone are exposed within the study area. The Gallup was penetrated in drilling. The general topographic relationships of these units, as well as structural features are shown on the geologic map of the Pinehaven 7.5 minute quadrangle (Plate I).

Scale 1:2,400

Figure 3

STRATIGRAPHIC COLUMN
PINEHAVEN QUADRANGLE

TERTIARY STRATIGRAPHY

UPPER BIDAHOCHI FORMATION--Sediments of the upper member of the Bidahochi Formation (Reagan, 1924) cap the mesa tops of the Pinehaven quadrangle except in the easternmost part. Cooley and Akers (1961) assign a Middle Pliocene age to this member. As noted by McCann (1938), these sediments rest unconformably on a westward-sloping surface of beveled Upper Cretaceous rocks in the Pinehaven area and older rocks to the west. The elevation of the base of the Bidahochi drops from approximately 7,460 ft in the northeast to about 7,100 ft to the southwest. This drop in elevation of this contact is gradual throughout the quadrangle, except near the eastern margin of the area.

The unconsolidated upper Bidahochi member sediments are composed mainly of reddish-brown to whitish, argillaceous, medium to fine grained sandstone along with lesser amounts of brown, nodular, resistant sandstone, minor white, biotite-bearing volcanic ash beds and some porous limestone beds. The sandstone is generally lighter in color when the carbonate content is greater. Exposures of the poorly consolidated Bidahochi sediments are characteristically covered by colluvial material except for a few steep slopes or under some resistant beds along mesa tops. Resistant sandstone or white tuff beds often hold up the upper surface of the Bidahochi. Usually the uppermost Bidahochi shows some signs of reworking, as indicated by the presence of a lag gravel containing pebbles of chert, quartzite and Cretaceous

sandstone or a veneer of eolian sand. The author agrees with McCann's (1938) suggestion that the upper surface of the Bidahochi Formation may have been reworked by wind in Pleistocene and Holocene time throughout the Gallup-Zuni area. For this reason the Bidahochi is mapped as Quaternary and Tertiary in age. The thickness of the Bidahochi sediments ranges from a knife edge to as much as 180 ft with an average of about 60 ft. Headward-cutting tributaries of the major drainages are slowly stripping away the Tertiary sediments.

UPPER CRETACEOUS STRATIGRAPHY

INTRODUCTION--The major coal-bearing rocks of the Pinehaven quadrangle are the Gallup Sandstone and Crevasse Canyon Formation and these are the only Upper Cretaceous rocks that outcrop. Figure 3 is a generalized stratigraphic column, showing the Crevasse Canyon Formation and the position of the major coal horizons present in the Pinehaven quadrangle. Below the Gallup, in the subsurface, is another interval of non-marine, coal-bearing rocks, termed the lower part of the Gallup Sandstone (Pike, 1947, Molenaar, 1973). Exploration and water well drilling indicate that the coals in this interval are too thin in the Pinehaven area to be of economic significance. This lower Gallup interval thins to the north, pinching out into the Mancos Shale, and thickens to the south at the expense of the Mancos (Molenaar, 1973).

GALLUP SANDSTONE--The Gallup Sandstone was named by Sears (1925) for exposures in the vicinity of the town of Gallup, New Mexico.

The well-known section in the hogback, east of Gallup, consists of three prominent ledges of sandstone and two intervening softer shaly intervals. The whole formation ranges from 220 to 280 ft in thickness. The two lower sands and the intervening sandy shale unit are marine in origin, while the upper soft interval is nonmarine and contains one or more coal beds. The uppermost Gallup sandstone is a 30- to 60-ft-thick, pink, coarse-grained, arkosic, fluvial sandstone. This unit thins to the north and east of Gallup, but is a persistent horizon to the south through the Gallup-Zuni basin (Dane and others, 1957). Molenaar (1973) has proposed naming and mapping this upper sandstone as the Torrivio Sandstone Member of the Gallup.

Only the uppermost 20 ft of the Gallup Sandstone is exposed in the central part of sec. 16, T. 12 N., R. 18 W. These limited exposures are of tan, fine-grained, well sorted sandstone. Internally the sandstone is composed of 1 to 3-ft-thick tabular to wedge-shaped beds with high-angle cross lamination. The cross sets have a common northwesterly dip direction.

CREVASSE CANYON FORMATION--Allen and Balk (1954) named this formation for the continental and nearshore rocks in the interval between the Gallup Sandstone and the Point Lookout Sandstone, as exposed near Crevasse Canyon in San Juan County, New Mexico. In the type area, the Crevasse Canyon Formation consists of the Dilco Coal Member, the Dalton Sandstone, and the Gibson Coal Member, in ascending order. The Bartlett Barren Member (Sears, 1925) is also recognized as a part of the Crevasse Canyon Formation and represents the landward equivalents of the marine Dalton

Sandstone. Both the Dalton and Point Lookout sandstones pinch out north of Gallup, thus eliminating convenient persistent breaks in the continental section. This results in the Gibson being overlain and hence, indistinguishable from the Cleary Coal Member of the Menefee. These two units are mapped together as part of the Crevasse Canyon. The Bartlett Barren Member of the Gallup-Zuni sag is distinguished from the Dilco and Gibson members on the basis of its lack of thick coals and as such has very imprecise boundaries. Sears (1925) divided the Crevasse Canyon in the Gallup area as follows: the Dilco Coal Member - the lower 240 to 300 ft, the Bartlett Barren Member - the medial 330 to 440 ft, and the combined Cleary and Gibson Coal Members - the upper 150 to 175 ft. Recent investigators in the Gallup East Quadrangle (Green and Jackson, 1976) were unable to follow these same divisions and combined all units from the Dilco up through the Cleary as the Crevasse Canyon undivided. The large amount of cover and the lack of readily identifiable boundaries between the members of the Crevasse Canyon in the Pinehaven area caused the present writer to map the rocks overlying the Gallup as Crevasse Canyon undivided.

The Crevasse Canyon is thinnest in the southwest quarter of the study area and thickens to the north and east. Over 980 ft of Crevasse Canyon strata have been penetrated by a Bokum drill hole in sec. 5, T. 12 N., R. 17 W., and projections from structural data indicate there may be 1500 ft of these strata in the northeast corner of the area. This thickness is greater than the equivalent Crevasse Canyon section of Sears (1925) near Gallup. Although not mappable on the surface, coal-bearing and

noncoal-bearing portions of the Crevasse Canyon can be recognized on cross sections constructed from drill hole data. These divisions, discussed in more detail in the coal geology section, may or may not correspond to the Dilco, Bartlett Barren, and Gibson-Cleary Members of the Crevasse Canyon Formation.

Lithologically, the Crevasse Canyon Formation of the Pinehaven area consists of varying amounts of sandstone, siltstone, shale, and coal. The presence or absence of coal has been the criteria for dividing the Crevasse Canyon into members. Therefore, since the other lithologic constituents are similar throughout the formation it is reasonable to describe them for the formation as a whole, rather than for each member unit.

The sandstones of the Crevasse Canyon Formation are composed of fine to medium quartz grains, with minor feldspar and chert. The grains are generally subangular to subrounded and moderately to poorly cemented. The sandstones occur as yellow to tan lenticular bodies up to 25 ft thick. These bodies have sharp, often erosional, lower contacts along which clay rip-up clasts are present. Internally the sand bodies consist of low- to high-angle, cross-cutting, trough cross beds. Particles within these bodies may show a fining upward, but more commonly show an upward decrease in the scale of cross-bedding and often exhibit ripple bedding at the top.

Shales of the Crevasse Canyon are of two types; carbonaceous and noncarbonaceous. The carbonaceous shales are generally brown to grayish-black and may contain petrified wood or iron-rich concretions. These shales are closely associated with coals. The

noncarbonaceous shales are yellowish-green to yellowish-gray or tan and also contain petrified wood. Both are commonly silty with minor laminations and thus can be termed mudstones.

Yellow or tan siltstone is the other major lithotype in the Crevasse Canyon. It is often in gradational contact with the silty noncarbonaceous shales or the silty sandstones.

Petrified wood is the most common type of fossil and is found throughout the Crevasse Canyon section. Several types of wood exist based on hand specimen appearance. Leaf impressions and seed casts may be found locally. Only a few scattered vertebrate remains were found. Fragments of chelonid carapaces were found in the lower part of the Crevasse Canyon at two locations; one in sec. 12, T. 12 N., R. 18 W. and one in sec. 18, T. 12 N., R. 17 W. Possible "dinosaur" bone scraps were locally in sec. 15 T. 13 N., R. 17 W. No identification of these bone fragments or their exact age was possible.

COAL GEOLOGY

STRATIGRAPHY--The coal geology discussed here is only that of the Crevasse Canyon portion of the Upper Cretaceous section. Coal also occurs within the Gallup Sandstone and the "lower Gallup" interval (as used by Molenaar, 1973, 1974); however, because of the lack of data on these coals and their generally thin and uneconomic nature, they will not be discussed. The Crevasse Canyon strata of the study area are comprised of two coal-bearing

intervals and an intervening relatively barren interval. This conclusion is drawn from the compilation of coal occurrence data from outcrops and exploration holes onto several cross sections, Plate II (a, b, c).

The lower 350 ft of the Crevasse Canyon, probably equivalent to the Dilco Coal Member, is the most important coal-bearing horizon. Coals of this interval crop out primarily in secs. 9, 13, 16, 23, and 24 of T. 12 N., R. 18 W. Coals occur throughout this interval but the thickest and most persistent coal horizons are found approximately 100 and 200 ft above the top of the Gallup Sandstone. Coal beds in this lower coal-bearing interval average about 2.0 ft thick, but locally reach over 6.0 ft thick. In some places the aggregate thickness of several thinner coal seams within a 20 ft zone totals as much as 7.4 ft. As many as 13 coal beds thicker than one foot occur within the lower coal-bearing interval. The coal beds are highly lenticular, but appear to be traceable for a distance of several miles. In general, these lower coal beds thicken and become more numerous toward the eastern side of the quadrangle toward the axis of the Allison syncline.

Above the lower coal-bearing horizon is an essentially barren interval roughly 300 ft thick which may be correlative with the Bartlett Barren Member of the Crevasse Canyon. Some thin, lenticular coal beds of very limited lateral extent are found in this interval, however; lithologically this interval is dominated by sandstone channel deposits. The ubiquitous channel sandstones have commonly scoured through the few thin coals present in this zone is the major factor in the coals lack of persistence.

Overlying the medial barren interval is another coal bearing portion of the Crevasse Canyon. As much as 900 ft of strata comprise this interval and are probably equivalent to the Gibson-Cleary Members undivided and possibly even part of the Allison Member of the Menefee Formation. Coal occurs mainly in the lowest 250 ft of this interval. Good exposures of these lowermost coals occur in T. 12 N., R. 17 W. on the Zuni Indian Reservation (Plate 3). The coal beds in the basal part of the upper coal interval range from 1.0 to 4.6 ft thick, but generally average 1.5 ft thick. Coal beds are generally thinner and not laterally persistent above the basal part. The maximum measured thickness of coal in the upper part of the upper coal interval is 2.0 ft. Unlike the lower coal-bearing interval, coal beds in the upper coal-bearing interval do not show any distinct thickening or abundance trends.

COAL ANALYSES--Analyses of the coals sampled was done by Hazen Laboratories of Golden, Colorado. Table 1 gives a breakdown of the Btu, proximate and ultimate analyses of four coal seams penetrated by drilling, and compares them to average analyses of Mesaverde Group coals. The description of these cores can be found in Appendix I. The two coals present in drill hole 1318-26-1 have a thickness of 3.2 ft at a depth of 113.6 ft and 3.6 ft at a depth of 189.4 ft. Hole 1218-14-1 has a coal at a depth of 256.3 ft with a thickness of 2.6 ft. Hole 1218-9-1 has a 4.2 ft coal at a depth of 130.0 ft. The coals sampled have a depth sufficient enough to avoid the influence of surface oxidation. According to the method outlined in ASTM 388-77 these

	TOTAL	FORMS OF PYRITIC	SULFUR ORGANIC	SULFATE
1318-26-1 (113.6-116.8')	.57	.32	.25	0.0
1318-26-1 (189.4-193.0')	.35	.11	.24	0.0
1218-14-1 (256.3-258.9')	.71	.20	.51	0.0
AVERAGE MESAVERDE	.75	.35	.40	0.0

BTU VALUES AND RANK

	AS RECEIVED BTU	MOIST MINERAL MATTER FREE BTU	RANK
1318-26-1 (113.6-116.8)	7955	11132	SUBBITUMINOUS A
1318-26-1 (189.4-193.0)	6128	11114	SUBBITUMINOUS A
1218-14-1 (256.3-258.9')	11589	12816	H.V. C BITUMINOUS
1218-9-1	11255	13323	H.V. B BITUMINOUS

four coals vary in rank from subbituminous A to high volatile B bituminous. This compares favorably with the average rank (high volatile bituminous C) for Mesaverde coals. The average sulfur content of these four coals is .58%, less than the Mesaverde average of 1.1%. Drill hole 1218-9-1 is a sample collected from cuttings, and as a result the moisture content is low and the ash content is high.

The coals in hole 1318-26-1 are 730-800 ft above the Gallup and therefore from the upper coal zone, while the coals from holes 1218-14-1 and 1218-9-1 are 39-165 ft above the Gallup and from the lower coal zone. The coals from the two coal zones can be readily divided into two groups based on their analyses. The lower zone coals present in holes 1218-14-1 and 1218-9-1 have a slightly higher rank than the upper zone coals in hole 1318-26-1. The proximate and ultimate analyses of the coals drilled in holes 1218-14-1 and 1218-9-1 are superior to those of hole 1318-26-1 for all values except sulfur. The upper zone coals in hole 1318-26-1 have a lower total sulfur content than the lower zone coals. The few samples collected made establishing trends based on the organic/inorganic ratios of sulfur impractical. The two upper zone coals present in hole 1318-26-1 have higher ash and moisture contents than do either of the lower zone coals in holes 1218-14-1 or 1218-9-1, as would be expected for coals of subbituminous rank. The ash content of the coals present in holes 1318-26-1 is considerably higher than either of the other two coals sampled or the Mesaverde average. This ash content is even higher than what would be expected for subbituminous coals. A possible reason for

Table 3 -- Coal Resources of Pinehaven quadrangle (figures in millions of tons).

a) Measured coal resources in beds 1.2 to 2.5 ft thick

Area	0-250 ft	250-1000 ft
T. 12 N., R. 17 W.	2.40	2.23
T. 12 N., R. 18 W.	2.33	0.26
T. 13 N., R. 17 W.	1.55	2.35
T. 13 N., R. 18 W.	3.13	5.05
Total*	9.42	9.89

b) Measured coal resources in beds greater than 2.5 ft thick

Area	0-250 ft	250-1000 ft
T. 12 N., R. 17 W.	2.46	2.20
T. 12 N., R. 18 W.	0.93	1.01
T. 13 N., R. 17 W.	0.20	2.44
T. 13 N., R. 18 W.	1.60	4.50
Total*	5.19	10.15

c) Indicated coal resources for the whole quadrangle

Category	0-250 ft	250-1000 ft
beds 1.2-2.5 ft	23.10	48.22
beds >2.5 ft	21.45	53.48
Total*	44.55	101.70

* Figures are rounded and may not equal total

this could be that the coals are near the edge of a coal swamp. A second possibility could be a non uniform subsidence resulting in a greater influx of clays and silt into the coal swamp.

COAL RESOURCES--Coal resources were calculated using the system of the U.S. Department of the Interior (U.S. Geological Survey Bulletin 1450-B). In-place coal was assumed to weigh 1770 tons per acre-foot, that of subbituminous coals. A weight of 1800 tons per acre-foot is normally used for bituminous coals, but determination of which coals are bituminous or subbituminous is not practical from well logs so the more conservative figure was used for all coals. Coal resources were calculated for the measured and indicated categories; the lenticularity of the coals suggests that the inferred category is highly speculative. Figure 4 is a location map of drill holes available for resource calculation, showing the measured (smaller) and indicated (larger) spheres of influence. Note that hole number 4 (NMBMMR1318-28-1) has no coal, even though the measured and indicated spheres are shown. The resources are tabulated, for both the measured and indicated categories, by township, depth and thickness (Table 3). Data from both drill holes and surface exposures were used in determining measured resources, while only drill hole data was used for indicated resource calculations. Appendix II contains the drill hole summary sheets used for reserve calculations, with minable coals indicated by an asterisk (*). The cuttings descriptions of holes drilled by the New Mexico Bureau of Mines are located in Appendix III.

TABLE 4

SURFACE AND COAL OWNERSHIP
(figures rounded to nearest percentile)

OWNER -----	SURFACE -----	COAL -----
Zuni Pueblo	20%	20%
Navajo Tribe	50%	41%
Navajo Allotted	10%	0%
Private	13%	8%
U.S. Gov't	2%	26%
State	5%	5%

Figure 5--Surface ownership of the quadrangle.

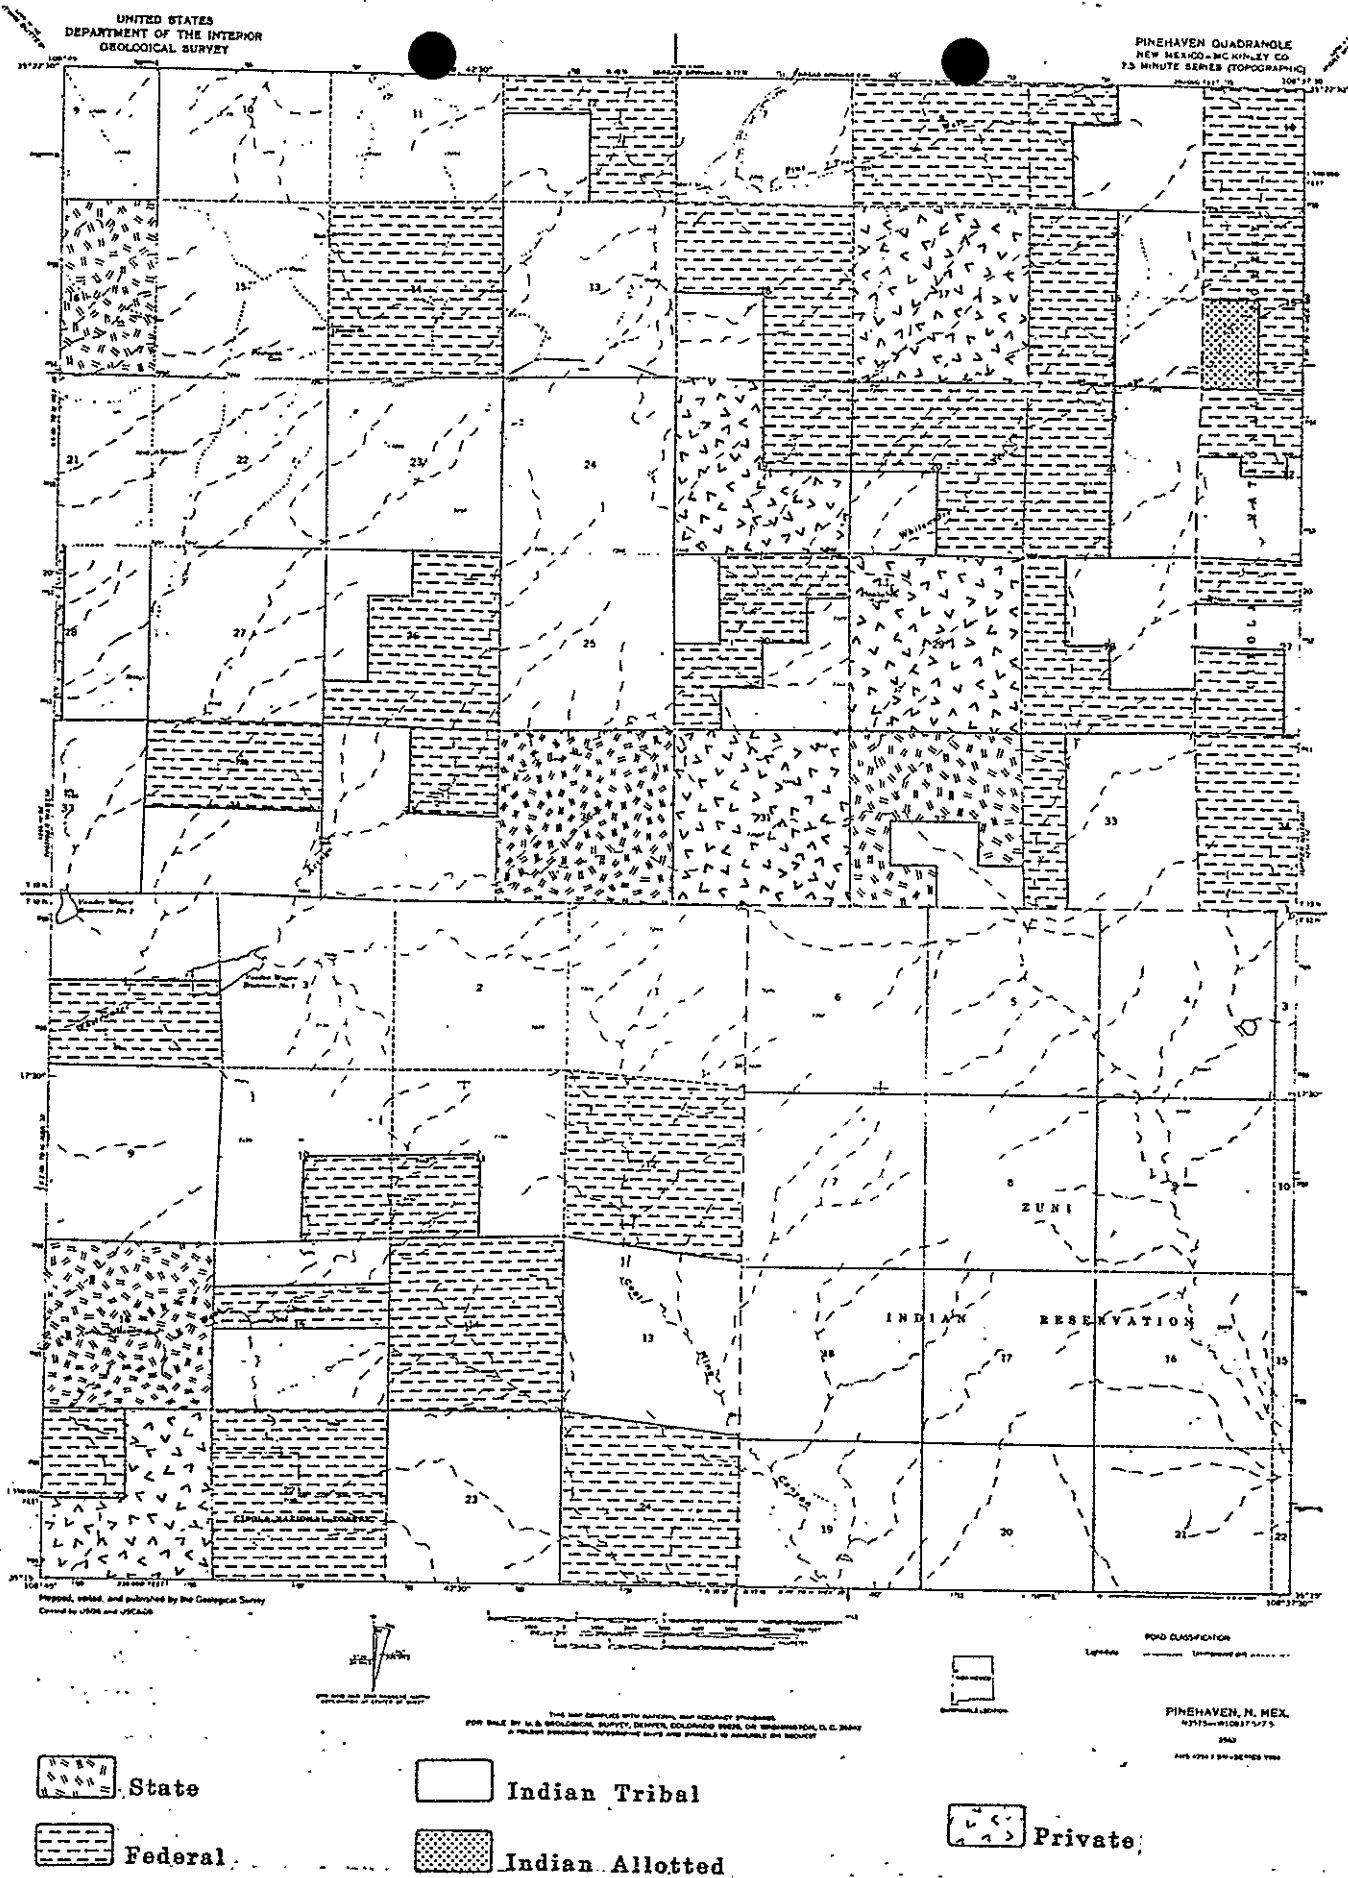

Figure 6--Coal ownership of the quadrangle.

Tabulation of measured coal resource data shows there are 34.65 million tons of in-place coal in this category. Of this amount, 15.34 million tons or 44% is from beds greater than 2.5 ft thick. The area covered by the measured coal resource calculations is small (Fig. 4) and probably only reflects 10% of the coal that may be present.

SURFACE AND COAL OWNERSHIP--Table 4 breaks down surface and coal ownership into percentages. Figure 5 shows the surface ownership by sections for the quadrangle and figure 6 does the same for coal ownership. The Zuni Tribe owns all of the surface and coal rights to approximately 20% of the Pinehaven quadrangle, the portion in T.12 N., R.17 W. Carbon Coal Company, a subsidiary of Hamilton Brothers Oil, has a coal exploration permit for that part of the Zuni Reservation and is in the process of trying to negotiate a lease and mining permit from the Zuni Indians.

Navajo Tribal trust or fee lands comprise 50% of the surface rights in the quadrangle, with holdings mainly in T. 12 N., R. 18 W. and T. 13 N., R. 18 W. The coal rights for 82% of these lands (41% of the quadrangle) are also vested with the Navajo Tribe; Tribal lands without coal rights for the most part have the coal rights held by the U.S. government. No known coal leases exist on any Navajo tribal lands.

Individual Navajo allotments make up 10% of the surface ownership, primarily in T.12N, R.18W. and T.13N., R.17W. No coal rights were conveyed with the allotments; the U.S. government reserved these rights. No leases are known for these lands.

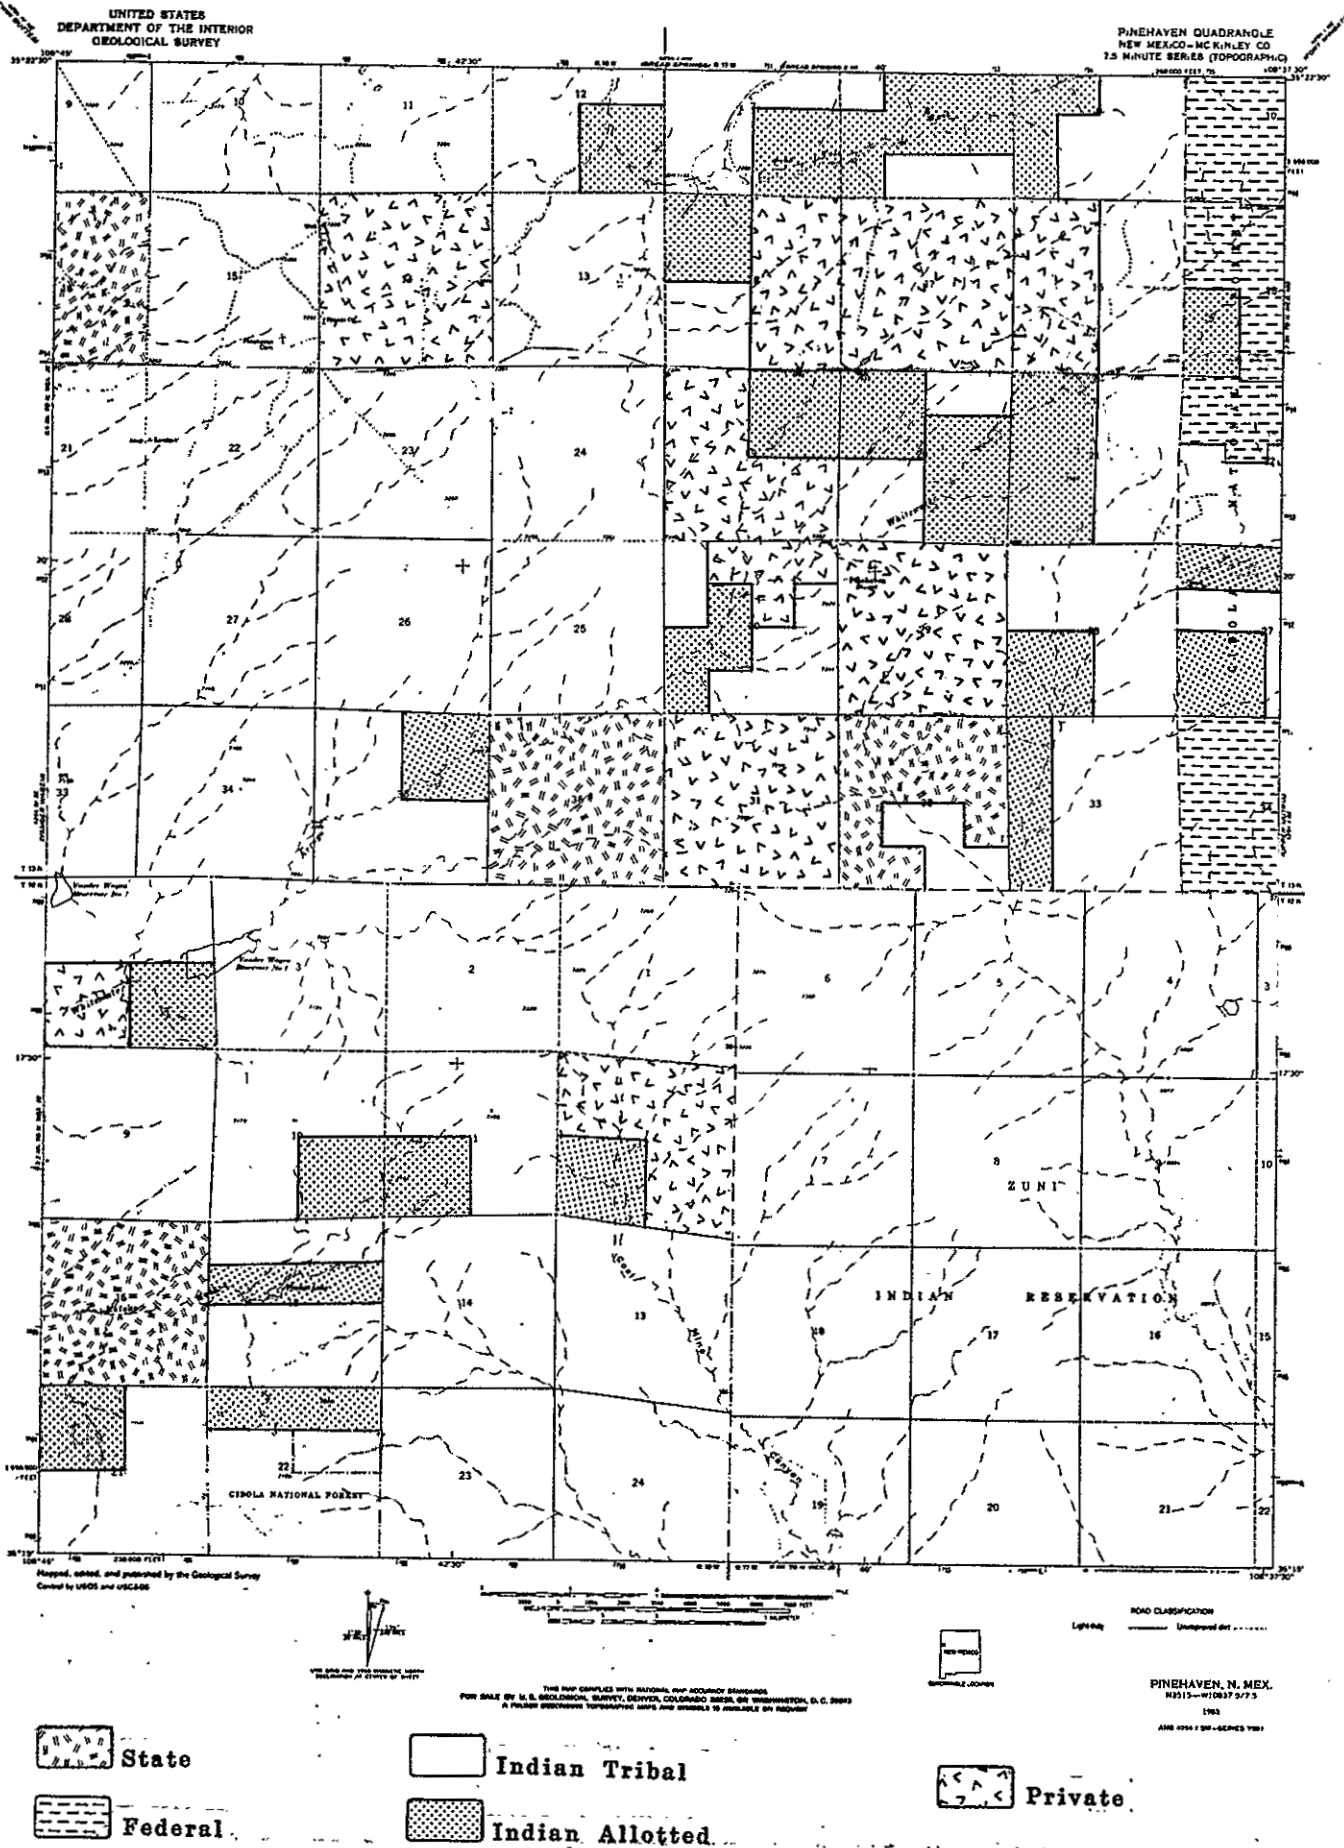

Figure 5--Surface ownership of the quadrangle.

Figure 6--Coal ownership of the quadrangle.

Private individuals hold 13% of the surface rights and 8% of the coal rights for the quadrangle. The amount of private coal ownership is less than the amount of private surface ownership, because of the patents issued on some of these lands reserved the coal right to the federal government.

The federal government owns the smallest amount of surface rights, 2%, but is the second largest owner of coal, retaining rights to the coal under 26% of the quadrangle. These extra coal rights underlie Navajo tribal, Navajo allotment or private surface. None of this coal has been leased.

The State of New Mexico owns the surface and coal rights for about 5% of the quadrangle. Some of the lands were leased for coal to Utah International, Incorporated, and to Carbon Coal Company but the leases have all been dropped. Data from drilling on these leases was kindly furnished by the companies and is included in this report.

COAL MINES AND EXPLORATION--There are no active or inactive coal mines or prospects in the Pinehaven quadrangle. Several small abandoned mines occur about 2.5 miles south of the study area in secs. 6 and 7, T.11N., R.17W. (Sears, 1925). The three mines in sec. 6 occur below the pink sandstone which forms the top of the Gallup (Torrevio Sandstone Member of Molenaar, 1973) in the "School Mine coal group" as named by Winchester (Sears, 1925) for one of the small mines there. The beds mined there are described as thin, not much more than 3 ft thick, and irregular in thickness; none of these coals are exposed in the Pinehaven quadrangle.

The mine in section 7 occurs in a still lower coal interval, the Pescado coal group (Sears, 1925), which is about 70 feet below the preceding coal interval. The coals of this group are highly lenticular and broken by many partings. Where mined, the coal was about 3 feet thick. Coal from this interval and the ones above were apparently used for heating at the Indian school at Blackrock, on the Zuni Reservation.

Two industry-oriented drilling programs for coal have been carried out in the Pinehaven area, one by Utah International, Incorporated and the other by Carbon Coal Company. Utah International conducted exploration drilling during 1974 on some state leases which were subsequently dropped. Three holes were drilled in sec. 36, T. 13 N., R. 17 W. in the study area. Three other holes were drilled immediately west of the study area, one in sec. 16, T. 13 N., R. 18 W. and two in sec. 32, T. 13 N., R. 18 W.

Carbon Coal also drilled on state leases, putting four holes in sec. 36, T. 13 N., R. 18 W. and one in sec. 32, T. 13 N., R. 17 W. Carbon Coal also relinquished its leases following its exploration program. The drilling information from the above programs is included in the appendix.

In addition to the drilling on state coal leases, Carbon Coal has done extensive exploration drilling on the Zuni Reservation, beginning in 1975. Carbon Coal applied for a mining lease in

1977, under the terms of its exploration permit, as a result of its earlier drilling findings (Maxwell and Nonini, 1977). Negotiations are still pending on the mining lease so no drilling information has been released. Part of the area drilled is within the Pinehaven quadrangle in T. 12 N., R. 17 W. The only available drill hole data for this part of the Zuni Reservation is a uranium test hole drilled by Bokum Resources (see appendix).

CONCLUSIONS

Strippable coal resources on the Pinehaven quadrangle consists of 14.61 million tons of measured coal and 44.55 million tons of indicated coal. This leaves a total of 121.74 million tons of deep coals in both the measured and indicated categories. Even though these coals have a rather high ash content, the sulfur content is very low.

Further exploratory drilling is recommended to the east, towards the axis of the Allison Syncline. This would indicate whether or not the lower coal zone does extend in this direction. The quality of these coals should improve, specifically in reduction of the ash, towards the center of the basin.

TOTAL COAL: 10.9'

Aggregate 10.9' 0-250': 2.0' 250-500': 7.4' 500'+: 1.5'
thickness in beds > 1.2 ft.

Mapped, edited, and published by the Geological Survey
Control by USGS and USC&GS
Topography by photogrammetric methods from aerial
photographs taken 1962. Field checked 1963
Polyconic projection. 1927 North American datum
10,000-foot grid based on New Mexico coordinate system, west zone
1000-meter Universal Transverse Mercator grid ticks,
zone 12, shown in blue
Fine red dashed lines indicate selected fence lines
